How long does a circuit breaker stay closed?

Though this seems simple, a circuit breaker remains closed for most of its life. It is only occasionally operated to open or close its contacts. Therefore, circuit breakers must operate reliably without any delay. To ensure this reliability, the operating mechanism is more complex than it first appears.

How do you close a circuit breaker?

To safely close a circuit breaker, the operating mechanism's springs must be charged. These springs store the energy required to close the main contacts. There are two methods to charge the springs: 1. Manual Charging Use the charging handle and pull it down six times until you hear a distinct "clack" sound.

What if the breaker is not ready to close?

The breaker is in the OFF position. The springs are fully charged. There is no active opening command. If the breaker is not ready when a closing command is issued: ? Cancel the command and retry once the breaker shows "ready to close." ? Press the mechanical ON pushbutton located on the breaker.

What if a breaker is not ready when a closing command is issued?

If the breaker is not ready when a closing command is issued: ? Cancel the command and retry once the breaker shows "ready to close." ? Press the mechanical ON pushbutton located on the breaker. To improve clarity, consider adding: Spring Charging Diagram - Manual vs. motor charging.

When should a circuit breaker open?

A circuit breaker should open quickly to limit contact erosion and interrupt faulty current promptly. However, the travel distance of the moving contact is also determined by the need to maintain a sufficient contact gap to withstand normal dielectric stresses and lightning impulse voltage when the breaker is open.

What happens if a circuit breaker hits a fixed contact?

During closing of contacts, the medium between contacts is replaced, hence sufficient mechanical power to be supplied during this circuit breaker operation to compress dielectric medium in the arcing chamber. After hitting fixed contact, the moving contact may bounce back, due to repulsive force which is not at all desirable.
