

How does electromagnetic catapult technology store energy

How much electricity does an electromagnetic catapult use?

The same energy is then used to return the carriage to its starting position. An electromagnetic catapult can launch every 45 seconds. Each three-second launch can consume as much as 100 million wattsof electricity,about as much as a small town uses in the same amount of time.

What technologies were developed for the electromagnetic catapult?

Two technologies successfully developed for the electromagnetic catapult were Pulse Power, which controls the electromagnetic catapult's power requirements and ensures precise and dependable launches, and Linear Electric Machine, which produces the electromagnetic force required to launch aircraft.

What is an electromagnetic catapult?

An electromagnetic catapult,also known as the electromagnetic aircraft launch system (EMALS) when specifically referring to the system used by the United States Navy,is a type of aircraft catapult that uses a linear induction motor system,rather than the single-acting pneumatic cylinder (piston) system in conventional steam catapults.

Can electromagnetic catapult technology be used to launch aircraft?

Electromagnetic catapult technology already has the ability to launch any aircraftnow in the Navy inventory and any the Navy has ordered. With the new launch system's potential to achieve acceleration forces reaching 14 Gs,human endurance may be one of the few limitations it faces.

How does a catapult work?

After hooking up to the carriage, aircraft are electro-magnetically pushed and pulled down the catapult until airborne. After releasing an aircraft at speeds approaching 200 mph, the carriage will come to a stop in only 20 feet, its forward movement countered by reversing the push-pull electromagnetic forces of the two beams.

What is a launch control system for electromagnetic catapults?

The launch control system for electromagnetic catapults, on the other hand, will know what speed an aircraft should have at any point during the launch sequence, and can make adjustments during the process to ensure that an aircraft will be within 3 mph of the desired takeoff speed.

Carriers equipped with four steam catapults have been able to use at least one of them 99.5% of the time. However, there are a number of drawbacks. One group of Navy engineers wrote: "The foremost deficiency is that the catapult operates without feedback control. With no feedback, there often occurs large transients
